HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

SABR TYPE STOCHASTIC VOLATILITY OPERATOR IN HILBERT SPACE

RAPHAEL DOUADY ZEYU CAO

ABSTRACT. In this paper, we define stochastic volatility operators in Hilbert space which are analogs to the widely-used SABR model [14] in finite dimensional case. We show the existence of the mild solution and some related regularity properties. Our proof is based on Leray-Schauder fixed point theorem and some priori inequalities on the stochastic operator processes we construct.

1. INTRODUCTION

It has been noticed for a long time that many financial problems could be naturally modeled with values in Banach spaces. Such ideas can be dated back to Douady [9], Musiela [16], etc. They are the pioneers who apply stochastic differential equations valued in Hilbert spaces to model the dynamics of evolution of instantaneous forward interest rate curves. Then Filipovic and his colleagues largely developed such methods, extended the classical Heath-Jarrow-Merton model and studied many further related geometric properties, see [10] [11] [12]. However, these methods mainly follow the no-arbitrage principle, and in the meantime, Cont, Bouchaud and etc [3] [18] suggested to model the forward interest rate curve as a vibrating string and added $D(x)\frac{\partial^2}{\partial x^2}$ as a regularizing term into their model. They argued that, although the model was not arbitrage-free, arbitrage opportunities were, in practice, eliminated by transaction costs. Such type of models gained increasing attention in recent years, in particular, after the 2008 financial crisis. One advantage of such an approach is that the regularity provided by this term avoids many issues of Filipovic's model, such as the wild behavior of the forward interest rate curve in the long run. A good comprehensive book which gives a nice overall introduction on this area is Carmona and Tehranchi [2]. Another way to model the evolution of interest rate curves is to use random field theory. D. P. Kennedy [15] is among the first to adopt such ideas. In a short remark at the end of his article, he also noticed and discussed the importance of the second order differential operator as a regularity term. An important and classic topic in interest rate modeling is stochastic volatility. Interest rate and volatility derivatives are very sensitive to the volatility of volatility, and many models on this aspect are introduced. SABR (stochastic alpha beta rho) model, Hagan and etc [14], is among the most popular and widely used and one of its key is that the volatility depends on some fractional power of the level of the forward rate. Such phenomena is also supported empirically, and its importance is discussed by Douady [8].

In this paper, we raise the question: how to construct infinite dimension version of stochastic volatility which is supposed to be a random process valued in some Hilbert space of operators. There is little work on such topics until recently Benth and Simonsen [1] introduce an infinite dimensional version of Heston stochastic volatility operator model. However, the volatility in their model is independent of the level of the forward rate curve. In order to handle SABR-type volatility operators, we develop two versions of models to relate volatility with level. One is a direct generalization of

Key words and phrases. Wiener Process in Hilbert Space, Stochastic Volatility, Operator Theory, Financial Modeling.

the classic SABR model while the other one is more general involving more non-linearity. Along with these volatility operator models, we include the regular term $D(x)\frac{\partial^2}{\partial x^2}$. And under some technical conditions, we show the existence of mild solutions to our models.

Another reason why we should investigate infinite dimensional models is that, similar to studying on fluid as a PDE on state functions and a dynamical system modeling each molecule inside in physics, it is usually better to consider a large set of assets as an infinite dimensional family first, then study it as a continuous mathematical object, that will be discretised for numerical purposes. Also, when performing any kind of calibration, one should always check its infinite dimensional limit. Indeed, there is a strong relationship between the stability of the numerical method in finite dimensions and the solvability in the infinite dimensional limit. Such views are discussed in more details by Douady [7].

The paper is organized as follows: in section 2, basic notations and mathematical results are introduced, we also give the construction of the stochastic volatility operator models and necessary conditions, then in section 3, we state and provide the detailed proof of the existence of mild solution to our model. Then we make our assumptions more realistic and natural by considering an Ornstein-Uhlenbeck process in section 4; in section 5, we generalize some regularity theorems with stochastic volatility operators; and we conclude this paper in section 6 with further remarks and plans for future work.

2. PRELIMINARIES AND MODEL CONSTRUCTION

In this section, we will introduce some necessary notations and basic results, then we will give the construction of our models.

2.1. Notations and Basic Settings. Now let's construct our model for instantaneous forward interest rate v_t with stochastic volatility operator Σ_t . Let \mathbb{H} denote the real Hilbert space $L^2(0, M)$ where M denotes the time to maturity of interest rates. We also fix some complete probability space $(\Omega, \mathcal{F}, \mathcal{F}_t, \mathbb{P})$, over which two Wiener processes are defined: a Q -Wiener process W_t and a R -Wiener process B_t ; both Q and R are covariance operators with finite trace. We also assume that there are two abstract real Hilbert spaces \mathbb{U} and \mathbb{V} , where W_t is \mathbb{U} -valued and B_t is \mathbb{V} -valued. Without loss of generality, we may assume that the filtration \mathcal{F}_t is generated by W_t and B_t . For \mathbb{U} (resp. \mathbb{V}), let \mathbb{U}_Q (resp. \mathbb{V}_R) denote a Hilbert subspace of \mathbb{U} (resp. \mathbb{V}) whose norm $(\cdot, \cdot)_Q$ (resp. $(\cdot, \cdot)_R$) is defined as $(g, h)_Q = (g, Q^{-1}h)_{\mathbb{U}}$ (resp. $(g, h)_R = (g, R^{-1}h)_{\mathbb{V}}$). Also, let $\mathbb{L}_2(\mathbb{U}_Q, \mathbb{H})$, $\mathbb{L}_2(\mathbb{U}_Q, \mathbb{R})$ and so forth denote the spaces of Hilbert-Schmidt Operator (HS-) between the two corresponding Hilbert spaces.

Now consider the unbounded operator

$$A = D(x)\frac{\partial^2}{\partial x^2} + \frac{\partial}{\partial x},$$

defined over \mathbb{H} whose domain $\mathcal{D}(A)$ is $H^2(0, M) \cap H_0^1(0, M)$, where $H^2(0, M)$ denotes the Sobolev space over the open interval $(0, M)$, consisting of all the L^2 - functions having second order derivative in L^2 and $H_0^1(0, M)$ denotes those in $H^2(0, M)$ with compact support. The function $D(x)$ is assumed strictly positive.

Let us now consider Δ_t a continuous deterministic process of mappings from \mathbb{H} to itself representing the drift of the yield curve process. We assume that for a.e. $(t, \omega) \in [0, T] \times \Omega$, $\Delta_t(\omega, \cdot)$ is \mathcal{F}_t -adapted and satisfies the integral condition (which we call Condition C in section 3.3.4): there exist two non-negative continuous functions f_1 and f_2 defined over $[0, T]$ such that

$$\text{for any } t \in [0, T] \text{ and any } h(x) \in \mathbb{H}, E\|\Delta_t(h(x))\|^2 \leq f_1(t)E\|h(x)\|^2 + f_2(t).$$

Then the model for the instantaneous forward rates is constructed as:

$$(2.1) \quad dv_t = Av_t dt + \Delta_t(v_t)dt + \Sigma_t(v_t)dW_t, \quad t \in [0, T], \quad v_0 \in \mathbb{H},$$

where Σ_t is the stochastic volatility operator process so that $\Sigma_t(v_t)$ is valued in the real Hilbert space $\mathbb{L}_2(\mathbb{U}_Q, \mathbb{H})$. The construction of it relies on another stochastic process σ_t valued in some abstract Hilbert space $\widetilde{\mathbb{H}}$ which will be specified below. Before that let's first look at some notations and classic results regarding the existence of σ_t .

Summary Our construction is: the yield curves are in space \mathbb{H} , driven by random noise $\mathbb{W}_t \in \mathbb{U}_Q$. The volatility operator process $\Sigma_t \in \mathbb{L}_2(\mathbb{U}_Q, \mathbb{H})$, and it's a function of another more elementary process σ_t , $\Sigma_t = F(\sigma_t)$, where $\sigma_t \in \widetilde{\mathbb{H}}$. Process σ_t is driven by noise $\mathbb{B}_t \in \mathbb{V}_R$. The volatility operator of volatility operator Σ_t , denoted as $G(t, \sigma_t)$, is valued in $\mathbb{L}_2(\mathbb{V}_R, \widetilde{\mathbb{H}})$. The exact forms of \mathbb{H} and function F will be specified in Model 1 and Model 2 introduced below.

2.2. Classic Results on Existence of Solutions for SDEs valued in Hilbert spaces. Now we can consider the initial value problem of stochastic evolution equations for the process σ_t in Hilbert spaces:

$$\begin{cases} d\sigma_t = \widetilde{A}\sigma_t + F(t, \sigma_t)\sigma_t + G(t, \sigma_t)d\mathbb{B}_t, & t \in (0, T) \\ \sigma_0 = h \in \widetilde{\mathbb{H}}, \end{cases}$$

where \widetilde{A} is a linear operator (possibly unbounded) defined on $\widetilde{\mathbb{H}}$ whose domain $\mathcal{D}(\widetilde{A})$ is dense in $\widetilde{\mathbb{H}}$ and \widetilde{A} generates a strongly continuous C_0 -semigroup Γ_t . Moreover, for a.e. $(t, \omega) \in [0, T] \times \Omega$, $F(t, \omega) : \widetilde{\mathbb{H}} \rightarrow \widetilde{\mathbb{H}}$ and $G(t, \omega) : \widetilde{\mathbb{H}} \rightarrow \mathbb{L}_2(\mathbb{V}_R, \widetilde{\mathbb{H}})$ are \mathcal{F}_t -adapted and predictable.

Usually the above problem does not have a strong solution (i.e. an actual solution lying in $\widetilde{\mathbb{H}}$), instead, people consider weak and mild solutions. Let's recall the definitions of these three types of solutions and their relations below.

Strong solution:

Consider an \mathcal{F}_t -adapted stochastic process σ_t satisfying:

$$\mathbb{P}\left(\int_0^T \|\widetilde{A}\sigma_t\|_{\widetilde{\mathbb{H}}} dt < \infty\right) = 1 \quad \text{and} \quad \mathbb{P}\left(\int_0^T (\|F(t, \sigma_t)\| + \|G(t, \sigma_t)\|^2) dt < \infty\right) = 1;$$

σ_t is a continuous process valued in $\widetilde{\mathbb{H}}$ and σ_t is in $\mathcal{D}(\widetilde{A})$ almost everywhere.

Then σ_t is a strong solution if for any $t \leq T$, almost surely,

$$\sigma_t = h + \int_0^t \tilde{A}\sigma_s + F(s, \sigma_s)ds + \int_0^t G(s, \sigma_s)dB_s.$$

Weak solution:

Consider an \mathcal{F}_t -adapted stochastic process σ_t satisfying:

$$\mathbb{P}\left(\int_0^T \|\sigma_t\|_{\tilde{\mathbb{H}}}^2 dt < \infty\right) = 1 \quad \text{and} \quad \mathbb{P}\left(\int_0^T (\|F(t, \sigma_t)\| + \|G(t, \sigma_t)\|^2) dt < \infty\right) = 1.$$

Then σ_t is a weak solution if for any $h \in \mathcal{D}(\tilde{A}^*)$ and $t \leq T$, \mathbb{P} -almost surely:

$$\langle \sigma_t, h \rangle = \langle \sigma_0, h \rangle + \int_0^t (\langle \sigma_s, \tilde{A}^* h \rangle + \langle F(s, \sigma_s), h \rangle) ds + \int_0^t \langle h, G(s, \sigma_s) dB_s \rangle,$$

where \tilde{A}^* denotes the dual map, and $\langle \cdot \rangle$ denotes the inner product of Hilbert space $\tilde{\mathbb{H}}$.

Mild solution:

Consider an \mathcal{F}_t -adapted stochastic process σ_t satisfying:

$$\mathbb{P}\left(\int_0^T \|\sigma_t\|_{\tilde{\mathbb{H}}}^2 dt < \infty\right) = 1 \quad \text{and} \quad \mathbb{P}\left(\int_0^T (\|F(t, \sigma_t)\| + \|G(t, \sigma_t)\|^2) dt < \infty\right) = 1.$$

The stochastic process σ_t is a mild solution if:

$$\sigma_t = \Gamma_t h + \int_0^t \Gamma_{t-s} F(s, \sigma_s) ds + \int_0^t \Gamma_{t-s} G(s, \sigma_s) dB_s.$$

In particular, a strong solution is a weak solution, and one can prove that a weak solution is a mild solution but not necessary conversely. The existence of strong solutions require very binding assumptions. However, if $E\left(\int_0^T \|G(t, \sigma_t)\|^2 dt\right) < \infty$, a mild solution is also a weak solution (see *Theorem 3.2* [13]), which is very useful for the future numerical implementation purpose. In practice, it is usually easier to prove the existence of mild solutions. For this reason, we first develop the existence theory of mild solutions in this paper.

We now present some classic results on the existence of solutions and some related properties which will be used later.

Theorem 2.1. (*Theorem 6.5 [5]*) For the above stochastic evolution equation problem, assume that:

1. For any $h \in \widetilde{\mathbb{H}}$, $t \in [0, T]$, $F(t, h, \omega)$ is a locally integrable $\widetilde{\mathbb{H}}$ -valued process, and $G(t, h, \omega)$ is predictable.

2. For some $p \geq 2$, there exist positive constants a_1 and a_2 such that

$$E \int_0^T [\|F(s, 0, \omega)\|^p + \|G(s, 0, \omega)\|_R^p] ds \leq a_1 ,$$

and for any $g \in \widetilde{\mathbb{H}}$,

$$\|F(t, g, \omega) - F(t, 0, \omega)\|^2 + \|G(t, g, \omega) - G(t, 0, \omega)\|_R^2 \leq a_2(1 + \|g\|^2) ,$$

for a.e. $(t, \omega) \in [0, T] \times \Omega$.

3. There exist a constant $c > 0$ such that, for any $g, h \in \widetilde{\mathbb{H}}$,

$$\|F(t, g, \omega) - F(t, h, \omega)\| + \|G(t, g, \omega) - G(t, h, \omega)\|_R \leq c\|g - h\| ,$$

for a.e. $(t, \omega) \in [0, T] \times \Omega$.

Then, for $h \in \widetilde{\mathbb{H}}$ and $p \geq 2$, the above initial value stochastic evolution equation problem has a unique mild solution σ_t , $0 \leq t \leq T$ with $\sigma_t \in C([0, T]; L^p(\Omega, \widetilde{\mathbb{H}}))$ such that

$$E\{ \sup_{0 \leq t \leq T} \|\sigma_t\|^p \} \leq K_p(T) \{ 1 + E \int_0^T [\|F(s, 0, \omega)\|^p + \|G(s, 0, \omega)\|_R^p] ds \} ,$$

for some constant $K_p(T) > 0$. For $p > 2$, the solution has continuous sample paths.

Lemma 2.1. (*Theorem 4.37 [6]*) Assume that $p \geq 2$ and let Φ be an $\mathbb{L}_2(\mathbb{U}_Q, \mathbb{H})$ -valued predictable process such that $E \int_0^T \|\Phi(s)\|^p ds < \infty$, then

$$E \sup_{0 \leq t \leq T} \left| \int_0^t \Phi(s) dW_s \right|^p \leq c_p \left[\int_0^T (E \|\Phi(s)\|_Q^p)^{\frac{2}{p}} ds \right]^{\frac{p}{2}} ,$$

where c_p is some positive constant. Moreover, if for any t , $t \mapsto \int_0^t \Phi(s) dW_s$ is continuous, then $\sup_{0 \leq t \leq T} \left\| \int_0^t \Phi(s) dW_s \right\|^p$ is measurable, and we can exchange sup and expectation.

2.3. Construction of Volatility Operator Process. First, apply **Theorem 2.1** with $p \geq 4$ to construct the process σ_t . Then we can claim that σ_t has continuous sample path and there exists a positive constant \widetilde{C} only depending on T such that for any $t \in [0, T]$, $E\|\sigma_t\|^p \leq \widetilde{C}$. Now, we propose two different kind of constructions of stochastic volatility operator models Σ_t using σ_t .

Model 1 (Infinite Dimension SABR) :

$\widetilde{\mathbb{H}} = \mathbb{L}_2(\mathbb{U}_Q, \mathbb{R})$, where \mathbb{R} denotes the space of real numbers. $p = 4$. The stochastic volatility operator Σ_t is defined as

$$\Sigma_t(h) = |h|^\beta \sigma_t ,$$

for any $h \in \mathbb{H}$, where $|\cdot|$ denotes the standard absolute value, $0 < \beta < 0.5$.

It is not hard to see that for any element $h \in \mathbb{H}$, $\Sigma_t(h) \in \mathbb{L}_2(\mathbb{U}_Q, \mathbb{H})$. Indeed,

$$\|\Sigma_t(h)\|_{\mathbb{L}_2(\mathbb{U}_Q, \mathbb{H})}^2 = \|h\|_{\mathbb{H}}^2 \|\sigma_t\|_{\mathbb{L}_2(\mathbb{U}_Q, \mathbb{R})}^2,$$

and also notice that if $h \in \mathbb{H}$, then so is $|h|^\beta$.

Model 2 (A general nonlinear volatility operator model):

First, let's embed \mathbb{H} into $\mathbb{L}_2(\mathbb{H}_Q, \mathbb{H})$: choose some unitary element e in \mathbb{H}_Q , consider

$$\iota : \mathbb{H} \rightarrow \mathbb{L}_2(\mathbb{H}_Q, \mathbb{H})$$

$$h \mapsto h \otimes \langle e, \cdot \rangle,$$

this is an isometric embedding, thus, \mathbb{H} can be regarded as a subspace of $\mathbb{L}_2(\mathbb{H}_Q, \mathbb{H})$.

Now assume that $P(x)$ is a polynomial of degree d of one variable, and let \mathbb{U} be $\mathbb{L}_2(\mathbb{H}_Q, \mathbb{H})$, and $\widetilde{\mathbb{H}}$ be $\mathbb{L}_2(\mathbb{L}_2(\mathbb{H}_Q, \mathbb{H}), \mathbb{L}_2(\mathbb{H}_Q, \mathbb{H}))$, then by **Theorem 2.1** (with $4d \leq p$) we get the $\widetilde{\mathbb{H}}$ -valued process σ_t , and the stochastic volatility operator $\Sigma_t(\cdot)$ is defined as the restriction of $P(\sigma_t(|\cdot|^\beta))$ on \mathbb{H} , $0 < \beta < 0.5$.

The whole construction can be summarised by the following diagrams:

$$\sigma_t(|\cdot|^\beta) : \mathbb{L}_2(\mathbb{H}_Q, \mathbb{H}) \rightarrow \mathbb{L}_2(\mathbb{L}_2(\mathbb{H}_Q, \mathbb{H}), \mathbb{L}_2(\mathbb{H}_Q, \mathbb{H}))$$

$$v_t \rightarrow \sigma_t(|v_t|^\beta)$$

The commutative diagram for construction of Σ_t :

$$\begin{array}{ccc} \mathbb{H} & \xrightarrow{\Sigma_t(v_t)} & \in \mathbb{L}_2(\mathbb{L}_2(\mathbb{H}_Q, \mathbb{H}), \mathbb{L}_2(\mathbb{H}_Q, \mathbb{H})) \\ \downarrow \iota & \nearrow & \\ \mathbb{L}_2(\mathbb{H}_Q, \mathbb{H}) & & P(\sigma_t(|v_t|^\beta)) \end{array}$$

Remark: for any element $h \in \mathbb{H}$ and any element $\omega \in \Omega$, consider the norm and its upper bound of $\Sigma_t(\omega, h)$.

$$\|\Sigma_t(\omega, h)\|_{\mathbb{L}_2(\mathbb{H}_Q, \mathbb{H})} \leq \|\Sigma_t(\omega, \cdot)\|_{\mathbb{L}(\mathbb{L}_2(\mathbb{H}_Q, \mathbb{H}), \mathbb{L}_2(\mathbb{H}_Q, \mathbb{H}))} \|h\|_{\mathbb{H}} \leq \|\Sigma_t(\omega, \cdot)\|_{\mathbb{L}_2(\mathbb{L}_2(\mathbb{H}_Q, \mathbb{H}), \mathbb{L}_2(\mathbb{H}_Q, \mathbb{H}))} \|h\|_{\mathbb{H}},$$

where $\mathbb{L}(\mathbb{H}_Q, \mathbb{H})$ denotes the space of bounded linear operators between two real Hilbert spaces. Notice that $\|\Sigma_t(\omega, \cdot)\|_{\mathbb{L}_2(\mathbb{L}_2(\mathbb{H}_Q, \mathbb{H}), \mathbb{L}_2(\mathbb{H}_Q, \mathbb{H}))} = \|P(\sigma_t(\omega, |\cdot|^\beta))\|_{\mathbb{L}_2(\mathbb{L}_2(\mathbb{H}_Q, \mathbb{H}), \mathbb{L}_2(\mathbb{H}_Q, \mathbb{H}))}$, thus, if we want to control its expectation by the expectation of norm of σ_t , we need to assume that $p \geq 4d$.

3. MAIN THEOREM AND ITS PROOF

Now we are ready to state our main theorem and its proof.

3.1. Main Theorem.

Theorem 3.1. *Let's first recall our model and the assumptions, the evolution equation of yield curve v_t is, defined as in (2.1),*

$$dv_t = Av_t dt + \Delta_t(v_t)dt + \Sigma_t(v_t)dW_t, \quad t \in [0, T], \quad v_0 \in \mathbb{H},$$

where $A = D(x)\frac{\partial^2}{\partial x^2} + \frac{\partial}{\partial x}$, an unbounded elliptic operator; Δ_t is the drift term satisfying Condition C; and the stochastic volatility operator process Σ_t is a function of the elementary process σ_t defined above in Model 1 and Model 2, where σ_t satisfies

$$\begin{cases} d\sigma_t = \tilde{A}\sigma_t + F(t, \sigma_t)\sigma_t + G(t, \sigma_t)dB_t, & t \in (0, T) \\ \sigma_0 = h \in \tilde{\mathbb{H}}, \end{cases}$$

where \tilde{A} , $F(t, \cdot)$ and $G(t, \cdot)$ satisfy the conditions in **Theorem 2.1** and **Lemma 2.1**, then operator A generates a compact, analytic, strongly continuous semigroup, and **Problem (2.1)** has at least one mild solution.

Remark Indeed, Condition C is very important to the existence of global mild solution, and we will show that by our construction of Model 1 and Model 2, the volatility operator process $\Sigma_t(\cdot)$ also satisfies Condition C.

3.2. Proof of Main Theorem.

3.2.1. *Step 1.* In this part, we prove that the operator A generates a compact, analytic, strongly continuous semigroup.

Let's follow the definitions in [17]. The principal part of A is $D(x)\frac{\partial^2}{\partial x^2}$ and it is strongly elliptic of order $2m$ ($m = 1$) due to the assumption of $D(x)$.

Then by Gårding's inequality (Theorem 2.2 Chapter 7 [17]), there exist $c_0 > 0$, $\lambda_0 \geq 0$ such that for any $u \in \mathcal{D}(A)$,

$$Re(-Au, u)_0 \geq c_0 \|u\|_{1,2}^2 - \lambda_0 \|u\|_{0,2}^2.$$

By Theorem 2.3 Chapter 7 [17], for any λ satisfying $Re\lambda \geq \lambda_0$, and every $f \in \mathbb{H}$, there exists a unique $u \in \mathcal{D}(A)$ such that

$$Au - \lambda u = f,$$

which indicates that $A - \lambda Id$ is full. Then by Theorem 2.7 Chapter 7 [17], A generates an analytic semigroup $\{G_t\}_{t \geq 0}$.

Due to Theorem 4.29 Chapter II [10], to show A generates an immediately compact semigroup (in other words, for any $t > 0$, G_t is compact), one only needs to show :

1. $\{G_t\}_{t \geq 0}$ is immediately norm continuous, in other words, G_t is norm continuous for any $t > 0$.

2. A has compact resolvent.

Indeed, part 1 is true since A generates an analytic semigroup. To show that A has a compact resolvent, we need the following result (Exercise 4.30 (4) Chapter II [10]):

Let $X = L^2(\tilde{\Omega})$, $\tilde{\Omega}$ is a bounded interval in \mathbb{R} . If $(A, \mathcal{D}(A))$ is an operator on X without empty resolvent set and $\mathcal{D}(A) \subset W^{1,2}(\tilde{\Omega})$, then A has compact resolvent.

In our case, $\tilde{\Omega}$ is $(0, M)$, by notation and definition, $\mathcal{D}(A) \subset H_0^1(0, M) = W_0^{1,2}(0, M) \subset W^{1,2}(0, M)$, thus, we only need to show that $\rho(A) \neq \emptyset$.

However, by definition of resolvent set ρ of a closed unbounded operator, we have $\rho(A) \neq \emptyset$ since for any λ , $\operatorname{Re} \lambda \geq \lambda_0$, $\lambda \operatorname{Id} - A$ is bijective between $\mathcal{D}(A)$ and \mathbb{H} . Notice that A is closed since it generates strongly continuous semigroup, see Theorem 1.4 Chapter II [10].

3.2.2. Step 2. Preparation

The set of all strongly measurable, square-integrable \mathbb{H} -valued random variables, denoted by $L^2(\Omega, \mathbb{H})$, is a Hilbert space with norm $\|v(\cdot)\|_{L^2} = (E(\|v(\cdot, \omega)\|^2))^{\frac{1}{2}}$. A subspace is $L_0^2(\Omega, \mathbb{H}) = \{v \in L^2(\Omega, \mathbb{H}) : v \text{ is } \mathcal{F}_0\text{-measurable}\}$.

Let I denotes some closed finite subinterval of $[0, \infty)$. Let $C(I, L^2(\Omega, \mathbb{H}))$ denote the space of all \mathcal{F}_t -adapted, measurable, and continuous (mean-squared continuous) processes from I to $L^2(\Omega, \mathbb{H})$ satisfying $\sup_{t \in I} E(\|v(t)\|^2) \leq \infty$. It is easy to see that such a space is a Banach space with norm:

$$\|v\|_C := (\sup_{t \in I} E(\|v(t)\|^2))^{\frac{1}{2}}.$$

Now, based on the definition of mild solution, let's define an operator Ψ on $C(I, L^2(\Omega, \mathbb{H}))$, assuming $I = [t_0, t_0 + \delta]$ where δ is some small positive real number:

$$\Psi(v_t) := G_{t-t_0} v_{t_0} + \int_{t_0}^t G_{t-s} \Delta_s(v_s) ds + \int_{t_0}^t G_{t-s} \Sigma_s(v_s) dW_s, \quad t \in I.$$

3.2.3. Step 3. In this part, we will show that the operator Ψ is well-defined, in other word, its image is in $C(I, L^2(\Omega, \mathbb{H}))$, and it is a continuous map between Banach spaces.

1) $\Psi(v_t) \in C(I, L^2(\Omega, \mathbb{H}))$

$$\begin{aligned} E(\|\Psi(v_t)\|^2) &\leq E(\|G_{t-t_0} v_{t_0}\|^2 + \|\int_{t_0}^t G_{t-s} \Delta_s(v_s) ds\|^2 + \|\int_{t_0}^t G_{t-s} \Sigma_s(v_s) dW_s\|^2) \\ &\leq 3E(\|G_{t-t_0} v_{t_0}\|^2) + 3E(\|\int_{t_0}^t G_{t-s} \Delta_s(v_s) ds\|^2) + 3E(\|\int_{t_0}^t G_{t-s} \Sigma_s(v_s) dW_s\|^2). \end{aligned}$$

Let $M(t_0)$ be $\max_{t \in I} \|G_t\|$, then apply Lemma 2.1 with $p = 2$,

$$E\|\Psi(v_t)\|^2 \leq 3M(t_0)^2 \|Ev_{t_0}\|^2 + 3M(t_0)^2 E \int_{t_0}^t \|\Delta_s(v_s) ds\|^2 + 3\hat{c} \cdot M(t_0)^2 \int_{t_0}^t E\|\Sigma_s(v_s)\|^2 ds,$$

where \hat{c} is some positive constant. By our assumptions, it is clear that the first two terms are finite. Let's show that this still holds true for the last term:

For Model 1:

$$\int_{t_0}^t E\|\Sigma_s(v_s)\|^2 ds = \int_{t_0}^t E(\|\sigma_t\|^2 \| |v_t|^\beta \|^2) ds \leq \int_{t_0}^t (E\|\sigma_s\|^4)^{\frac{1}{2}} (E\| |v_s|^\beta \|^4)^{\frac{1}{2}} ds,$$

notice that $(E\|\sigma_s\|^4)^{\frac{1}{2}}$ is bounded by our assumption of Model 1, and

$$E\| |v_s|^\beta \|^4 = E\left(\int_0^M |v_s(x)|^{2\beta} dx\right)^2 \leq M^{2-2\beta} [E\left(\int_0^M |v_s(x)|^2 dx\right)^{2\beta}],$$

notice that $E\left(\int_0^M |v_s(x)|^2 dx\right)^{2\beta} \lesssim [E\left(\int_0^M |v_s(x)|^2 dx\right)]^{2\beta}$, which is bounded for any s .

For Model 2:

$$E\|\Sigma_t(v_t)\|^2 = E\|P(\sigma_t)(|v_t|^\beta)\|^2 \leq E\|P(\sigma_t)\|^2 \| |v_t|^\beta \|^2 \leq [E\|P(\sigma_t)\|^4]^{\frac{1}{2}} [E\| |v_t|^\beta \|^4]^{\frac{1}{2}},$$

and we already know that $[E\| |v_t|^\beta \|^4]^{\frac{1}{2}}$ is bounded from the analysis above in Model 1; notice that $E\|P(\sigma_t)\|^4 \lesssim E\|\sigma_t\|^{4d}$ since $P(x)$ is a polynomial of degree d . By our assumption for Model 2, this is also finite.

Thus, in either case the last integral term is finite, and we conclude that for any fixed $t \in I$, $\Psi(v_t) \in L^2(\Omega, \mathbb{H})$.

Moreover, to show the process $\psi(v_t)$ is continuous from I to $C(I, L^2(\Omega, \mathbb{H}))$, one only needs to show that as $s \rightarrow t$, $E\|\Psi(v_s) - \Psi(v_t)\|^2 \rightarrow 0$, but this is easy to see from the estimations for the two models above.

A Remark on the Upper Bound of β : We have assumed that $\beta < 0.5$, indeed, we can see from the arguments below that we only need this restriction instead of $\beta < 1$ to show that $E\|\Sigma_t(v_t)\|^2$ is finite in our two models above for a general σ_t , since we only assume that σ_t has finite 4 th (resp. $(4d)$ th) moment for Model 1 (resp. Model 2). Now, if the process σ_t has higher finite moments, or ideally, finite moments for any order, then we have the following arguments to increase the upper bound of β . Let's use Model 1 as an example to illustrate the idea, similar procedure works for Model 2.

Assume that $E\|\sigma_t\|^{4n} < \infty$, where n is some positive integer, then

$$\begin{aligned} \int_{t_0}^t E \|\Sigma_s(v_s)\|^2 ds &= \int_{t_0}^t E (\|\sigma_t\|^2 \| |v_t|^\beta \|^2) ds \leq \int_{t_0}^t (E \|\sigma_s\|^{4n})^{\frac{1}{2n}} (E \| |v_s|^\beta \|^{\frac{4n}{2n-1}})^{\frac{2n-1}{2n}} ds \\ &\lesssim \int_{t_0}^t (E \| |v_s|^\beta \|^{\frac{4n}{2n-1}})^{\frac{2n-1}{2n}} ds, \end{aligned}$$

thus only need to show $E \| |v_s|^\beta \|^{\frac{4n}{2n-1}}$ is bounded, in fact:

$$E \| |v_s|^\beta \|^{\frac{4n}{2n-1}} = E \left(\int_0^M |v_s(x)|^{2\beta} dx \right)^{\frac{2n}{2n-1}} \lesssim E \left(\int_0^M |v_s(x)|^2 dx \right)^{\frac{2n\beta}{2n-1}},$$

as long as $\frac{2n\beta}{2n-1} < 1$, we can apply Hölder's inequality to get the desired finiteness estimation:

$$E \left(\int_0^M |v_s(x)|^2 dx \right)^{\frac{2n\beta}{2n-1}} \lesssim [E \left(\int_0^M |v_s(x)|^2 dx \right)]^{\frac{2n\beta}{2n-1}},$$

in other words, the upper bound of β is $\frac{2n-1}{2n}$, which can be as close to 1 as desired with n large enough.

Such process σ_t with finite moments of high orders does exist and is indeed very natural, for instance, if σ_t is either Gaussian or CIR type, then we have the necessary finite moments conditions. In particular, the Ornstein-Uhlenbeck Process, which is considered in section 4, is a good example.

2) Let's show that $\Psi : C(I, L^2(\Omega, \mathbb{H})) \rightarrow C(I, L^2(\Omega, \mathbb{H}))$ is a continuous map between Banach spaces.

Clearly, we indeed only need to show that $v_t \mapsto \int_{t_0}^t G_{t-s} v_s dW_s$ is a continuous map.

Assume that v_t^n converges to v_t as $n \rightarrow \infty$ in $C(I, L^2(\Omega, \mathbb{H}))$, in other words, $\sup_{t \in I} E \|v_t^n - v_t\|^2$ converges to 0, as $n \rightarrow \infty$. Then for any n , let's estimate:

$$\int_{t_0}^t G_{t-s} \Sigma_s(v_s^n) dW_s - \int_{t_0}^t G_{t-s} \Sigma_s(v_s) dW_s = \int_{t_0}^t G_{t-s} \Sigma_s(v_s^n - v_s) dW_s,$$

For Model 1:

$$\begin{aligned} E \left\| \int_{t_0}^t G_{t-s} \Sigma_s(v_s^n - v_s) dW_s \right\|^2 &= E \left\| \int_{t_0}^t G_{t-s} \sigma_s (|v_s^n|^\beta - |v_s|^\beta) dW_s \right\|^2 \\ &\lesssim M(t_0)^2 \int_{t_0}^t E \left(\| |v_s^n|^\beta - |v_s|^\beta \| \cdot \|\sigma_s\| \right)^2 ds, \end{aligned}$$

due to Lemma 2.1.

Then

$$E \left\| \int_{t_0}^t G_{t-s} \Sigma_s(v_s^n - v_s) dW_s \right\|^2 \lesssim M(t_0)^2 \int_{t_0}^t \{E \|\sigma_s\|^4\}^{\frac{1}{2}} \cdot \{E \| |v_s^n|^\beta - |v_s|^\beta \|^4\}^{\frac{1}{2}} ds,$$

by assumption $E\|\sigma_s\|^4$ is uniformly bounded over I , thus,

$$E\left\|\int_{t_0}^t G_{t-s}\Sigma_s(v_s^n - v_s)dW_s\right\|^2 \lesssim \int_{t_0}^t \{E\| |v_s^n|^\beta - |v_s|^\beta \|^4\}^{\frac{1}{2}} ds.$$

For Model 2: apply Lemma 2.1,

$$\begin{aligned} E\left\|\int_{t_0}^t G_{t-s}\Sigma_s(v_s^n - v_s)dW_s\right\|^2 &= E\left\|\int_{t_0}^t G_{t-s}P(\sigma_s)(|v_s^n|^\beta - |v_s|^\beta)dW_s\right\|^2 \\ &\lesssim M(t_0)^2 \int_{t_0}^t E\|P(\sigma_s)(|v_s^n|^\beta - |v_s|^\beta)\|^2 ds. \end{aligned}$$

Notice that $\|P(\sigma_t)\|_{\mathbb{L}} \leq \|P(\sigma_t)\|_{\mathbb{L}_2}$, where $\|\cdot\|_{\mathbb{L}}$ denotes the norm of bounded operator and $\|\cdot\|_{\mathbb{L}_2}$ denotes the norm of Hilbert-Schmidt operator (which is the norm we consider here), then

$$E\|P(\sigma_s)(|v_s^n|^\beta - |v_s|^\beta)\|^2 \leq E\|P(\sigma_s)\|_{\mathbb{L}}^2 \|(|v_s^n|^\beta - |v_s|^\beta)\|^2 \leq E\|P(\sigma_s)\|_{\mathbb{L}_2}^2 \|(|v_s^n|^\beta - |v_s|^\beta)\|^2,$$

then by Holder inequality,

$$\int_{t_0}^t E\|P(\sigma_s)(|v_s^n|^\beta - |v_s|^\beta)\|^2 ds \leq M(t_0)^2 \int_{t_0}^t \{E\|P(\sigma_s)\|_{\mathbb{L}_2}^4\}^{\frac{1}{2}} \cdot \{E\| |v_s^n|^\beta - |v_s|^\beta \|^4\}^{\frac{1}{2}} ds,$$

by assumption of Model 2, $E\|P(\sigma_s)\|_{\mathbb{L}_2}^4 \lesssim E\|\sigma_s\|^{4d}$ is uniformly bounded for any $s \in I$, thus,

$$E\left\|\int_{t_0}^t G_{t-s}\Sigma_s(v_s^n - v_s)dW_s\right\|^2 \lesssim \int_{t_0}^t \{E\| |v_s^n|^\beta - |v_s|^\beta \|^4\}^{\frac{1}{2}} ds.$$

Thus, we only need to consider $E\| |v_s^n|^\beta - |v_s|^\beta \|^4$.

$$\begin{aligned} E\| |v_s^n|^\beta - |v_s|^\beta \|^4 &= \int_{\Omega} \left(\int_0^M | |v_s^n|^\beta - |v_s|^\beta |^2 dx \right)^2 d\mathbb{P} \leq \int_{\Omega} \left\{ \left(\int_0^M 1^{\frac{1}{1-\beta}} dx \right)^{2(1-\beta)} \cdot \left[\int_0^M | |v_s^n|^\beta - |v_s|^\beta |^{\frac{2}{\beta}} dx \right]^{2\beta} \right\} d\mathbb{P} \\ &\lesssim \int_{\Omega} \left[\int_0^M | |v_s^n|^\beta - |v_s|^\beta |^{\frac{2}{\beta}} dx \right]^{2\beta} d\mathbb{P} \lesssim \left(\int_{\Omega} 1^{\frac{1}{1-2\beta}} d\mathbb{P} \right)^{1-2\beta} \cdot \left[\int_{\Omega} \left[\int_0^M | |v_s^n|^\beta - |v_s|^\beta |^{\frac{2}{\beta}} dx \right] d\mathbb{P} \right]^{2\beta} \\ &\lesssim \left[\int_{\Omega} \left[\int_0^M | |v_s^n|^\beta - |v_s|^\beta |^{\frac{2}{\beta}} dx \right] d\mathbb{P} \right]^{2\beta}. \end{aligned}$$

Now, if we can bound $\int_{\Omega} \left[\int_0^M | |v_s^n|^\beta - |v_s|^\beta |^{\frac{2}{\beta}} dx \right] d\mathbb{P}$ by $E\|v_s^n - v_s\|^2$, then we are done. To do so, let's first consider the following lemma:

Lemma 3.2. *If a, b are two non-negative real numbers, and $0 < \beta < 1$, then $(|a^\beta - b^\beta|)^{\frac{2}{\beta}} \leq (a - b)^2$.*

Proof. If any number is zero, or they are equal, then the inequality is trivially correct, thus, we assume that neither of them is zero. Moreover, we may assume that $a > b$. Set $p = \frac{1}{\beta} > 1$, $x := b^\beta$, $y := (a - b)^\beta$.

For $p > 1$, it is clear that for any two positive numbers x and y , $(x + y)^p \geq x^p + y^p$. Thus, $(b^\beta + (a - b)^\beta)^p \geq (b^\beta)^p + ((a - b)^\beta)^p = a$, which implies that $b^\beta + (a - b)^\beta \geq a^{1/p} \Rightarrow (a - b)^\beta \geq a^{1/p} - b^\beta$, which is exactly what we need. \square

Now, according to Lemma 3.2, $||v_s^n|^\beta - |v_s|^\beta|^{\frac{2}{\beta}} \leq (|v_s^n| - |v_s|)^2 \leq (v_s^n - v_s)^2$, thus,

$$\int_{\Omega} \left[\int_0^M | |v_s^n|^\beta - |v_s|^\beta |^{\frac{2}{\beta}} dx \right] d\mathbb{P} \leq \int_{\Omega} \left[\int_0^M (v_s^n - v_s)^2 dx \right] d\mathbb{P} = E \|v_s^n - v_s\|^2 \leq \|v_s^n - v_s\|_C^2.$$

Thus, we can conclude that the operator Ψ is continuous, and if a fixed point of it exists, it must be a mild solution to Problem 3.1.

3.2.4. *Step 4.* In this part, let's first show that the stochastic volatility operator Σ_t defined in either model satisfy a similar condition as the drift term Δ_t :

There exist two non-negative continuous functions $\tau_1(t)$ and $\tau_2(t)$ from I to $[0, \infty)$ such that for any t in I ,

$$E \|\Sigma_t(v_t)\|^2 \leq \tau_1(t) E \|v_t\|^2 + \tau_2(t).$$

We call such kind of condition: Condition C.

For Model 1:

$$E \|\Sigma_t(v_t)\|^2 = E \|\sigma_t \cdot |v_t|^\beta\|^2 \leq (E \|\sigma_t\|^4)^{\frac{1}{2}} (E \| |v_t|^\beta \|^4)^{\frac{1}{2}} \lesssim (E \| |v_t|^\beta \|^4)^{\frac{1}{2}},$$

since $E \|\sigma_t\|^4$ is uniformly bounded.

Consider

$$\begin{aligned} (E \| |v_t|^\beta \|^4)^{\frac{1}{2}} &= \left(\int_{\Omega} \left[\int_0^M |v_t(\omega, x)|^{2\beta} dx \right]^2 d\mathbb{P} \right)^{\frac{1}{2}} \leq \left(\int_{\Omega} [M^{2(1-\beta)} \cdot \left(\int_0^M |v_t|^2 \right)^{2\beta}] d\mathbb{P} \right)^{\frac{1}{2}} \\ &\leq M^{(2-2\beta)} \cdot (E \|v_t\|^2)^{\beta} \leq M^{(2-2\beta)} \cdot (E \|v_t\|^2 + 1), \end{aligned}$$

the last inequality holds since if $E \|v_t\|^2 \geq 1$, then $(E \|v_t\|^2)^{\frac{\beta}{2}} \leq E \|v_t\|^2$, otherwise, $(E \|v_t\|^2)^{\beta} \leq 1$.

For Model 2:

$$E \|\Sigma_t(v_t)\|^2 = E \|P(\sigma_t)(|v_t|^\beta)\|^2 \leq (E \|P(\sigma_t)\|^4)^{\frac{1}{2}} (E \| |v_t|^\beta \|^4)^{\frac{1}{2}} \lesssim (E \| |v_t|^\beta \|^4)^{\frac{1}{2}},$$

since $P(\cdot)$ is a polynomial of degree d , $E \|P(\sigma_t)\|^4$ can be bounded by a function of $E \|v_t\|^{4d}$, which is uniformly bounded in Model 2. And for the rest part, we can simply copy the proof of Model 1.

Thus, we proved that both models satisfy Condition C.

The following Steps are inspired and modified from the proofs in [4], [19].

3.2.5. *Step 5.* In this part, we show the existence of a local mild solutions starting at point $t_0 \in [0, T)$.

Choose $\delta_1 > 0$ such that $[t_0, t_0 + \delta_1] \subset [0, T)$. Then set

$$\begin{aligned} M(t_0) &= \sup_{t \in [t_0, t_0 + \delta_1]} \{\|G_t\|\}, \\ R(t_0) &= 3M(t_0)(3E\|v_{t_0}\|^2 + 2), \\ \Gamma_1(t_0) &= \sup_{t \in [t_0, t_0 + \delta_1]} \{E\|\Delta_t(v_t)\|^2 \mid E\|v_t\|^2 \leq R(t_0)\}, \\ \Gamma_2(t_0) &= \sup_{t \in [t_0, t_0 + \delta_1]} \{E\|\Sigma_t(v_t)\|^2 \mid E\|v_t\|^2 \leq R(t_0)\}, \end{aligned}$$

here we use the facts that v_t is mean-squared continuous, and Δ_t, Σ_t satisfy Condition C.

Let Ξ denotes $\{v_t \in C(I, L^2(\Omega, \mathbb{H})) \mid E\|v_t\|^2 \leq R(t_0)\}$ which is a closed ball centered at 0 with radius $R(t_0)$.

By Lemma 2.1, we may assume that there exists a positive constant Θ such that for any I :

$$E\left\|\int_{t_0}^t G_{t-s}\Sigma_s(v_s)dW_s\right\|^2 \leq \Theta M(t_0)^2 \int_{t_0}^t E\|\Sigma_s(v_s)\|^2 ds.$$

Then set

$$\delta = \min\left\{\delta_1, \frac{E\|v_{t_0}\|^2 + 1}{\Gamma_1(t_0)}, \frac{E\|v_{t_0}\|^2 + 1}{\Theta\Gamma_2(t_0)}\right\}.$$

Then for any $v \in \Xi, t \in [t_0, t_0 + \delta]$,

$$\begin{aligned} E\|\Psi(v_t)\|^2 &\leq 3E\|G_{t-t_0}v_{t_0}\|^2 + 3E\left\|\int_{t_0}^t G_{t-s}\Delta_s(v_s)ds\right\|^2 + 3E\left\|\int_{t_0}^t G_{t-s}\Sigma_s(v_s)dW_s\right\|^2 \\ &\leq 3M(t_0)^2E\|v_{t_0}\|^2 + 3M(t_0)^2\Gamma_1(t_0)\delta + 3M(t_0)^2\Theta\Gamma_2(t_0)\delta \\ &\leq 3M(t_0)^2(3E\|v_{t_0}\|^2 + 2) = R(t_0), \end{aligned}$$

thus, Ψ maps Ξ into itself.

Then we show that $\Psi : \Xi \rightarrow \Xi$ is compact.

First, we show that $\{\Psi(v_t) \mid v_t \in \Xi\}$ is relatively compact in $L^2(\Omega, \mathbb{H})$ for any $t \in [t_0, t_0 + \delta]$. This is clear for $t = t_0$ since there is only one point.

In general, for $t > t_0, 0 < \varepsilon < t - t_0$, and $v_t \in \Xi$, define

$$\begin{aligned} \Psi^\varepsilon(v_t) &= G_{t-t_0}v_{t_0} + \int_{t_0}^{t-\varepsilon} G_{t-t_0}\Delta_s(v_s)ds + \int_{t_0}^{t-\varepsilon} G_{t-t_0}\Sigma_s(v_s)dW_s \\ &= G_{t-t_0}v_{t_0} + G_\varepsilon \int_{t_0}^{t-\varepsilon} G_{t-\varepsilon-t_0}\Delta_s(v_s)ds + G_\varepsilon \int_{t_0}^{t-\varepsilon} G_{t-\varepsilon-t_0}\Sigma_s(v_s)dW_s, \end{aligned}$$

since G_t is compact for any $t > 0$, $\{\Psi(v_t) \mid v \in \Xi\}$ is also relatively compact in $L^2(\Omega, \mathbb{H})$, for any ε .

Moreover, for any $v \in \Xi$, we have

$$\begin{aligned} E\|\Psi(v_t) - \Psi^\varepsilon(v_t)\|^2 &\leq 3E\left\|\int_{t-\varepsilon}^t G_{t-s}\Delta_s(v_s)ds\right\|^2 + 3E\left\|\int_{t-\varepsilon}^t G_{t-s}\Sigma_s(v_s)dW_s\right\|^2 \\ &\leq 3M(t_0)^2 \cdot [\Gamma_1(t_0) + \Theta\Gamma_2(t_0)]\varepsilon, \end{aligned}$$

thus, $\{\Psi(v_t)|v \in \Xi\}$ is arbitrarily close to relatively compact sets in $L^2(\Omega, \mathbb{H})$. Thus, for any $t \in [t_0, t_0 + \delta]$, $\{\Psi(v_t)|v \in \Xi\}$ is relatively compact.

Next, let's show that $\Psi(\Xi)$ is an equicontinuous family of functions in $C(I, L^2(\Omega, \mathbb{H}))$.

For any $v \in \Xi$, $t_0 \leq t_1 \leq t_2 \leq t_0 + \delta$, apply Lemma 2.1 to $G_{t_2-s}\Sigma_s(v_s)$ and $[G_{t_2-s} - G_{t_1-s}]\Sigma_s(v_s)$, we have

$$\begin{aligned} E\|\Psi(v_{t_1}) - \Psi(v_{t_2})\|^2 &\lesssim E\|G_{t_2-t_0}v_{t_0} - G_{t_1-t_0}v_{t_0}\|^2 + E\left\|\int_{t_1}^{t_2} G_{t_2-s}\Delta_s(v_s)ds\right\|^2 \\ &\quad + E\left\|\int_{t_0}^{t_1} [G_{t_2-s} - G_{t_1-s}]\Delta_s(v_s)ds\right\|^2 + E\left\|\int_{t_1}^{t_2} G_{t_2-s}\Sigma_s(v_s)dW_s\right\|^2 \\ &\quad + E\left\|\int_{t_0}^{t_1} [G_{t_2-s} - G_{t_1-s}]\Sigma_s(v_s)dW_s\right\|^2 \\ &\leq E\|G_{t_2-t_0} - G_{t_1-t_0}\|^2 + M(t_0)^2(t_2 - t_1)\Gamma_1(t_0) \\ &\quad + M(t_0)^2\Gamma_1(t_0) \int_{t_0}^{t_1} \|G_{t_2-s} - G_{t_1-s}\|^2 ds + \Theta M(t_0)^2(t_2 - t_1)\Gamma_2(t_0) \\ &\quad + \Theta M(t_0)^2\Gamma_2(t_0) \int_{t_0}^{t_1} \|G_{t_2-s} - G_{t_1-s}\|^2 ds, \end{aligned}$$

let's denote the five components of the right hand side of the last inequality above sequentially as ①, ②, ③, ④ and ⑤.

Since $G_{t-t_0}v_{t_0}$ is continuous on $[t_0, t_0 + \delta]$, it is uniformly continuous, thus, ① $\rightarrow 0$, as $(t_2 - t_1) \rightarrow 0$; Obviously, ② and ④ tend to 0 if $(t_2 - t_1) \rightarrow 0$. Now notice that G_t is compact for $t > 0$, we know that G_t is continuous in operator norm. Combining this fact with Lebesgue Dominated Convergence Theorem, we know that ③ and ⑤ also go to 0 if $(t_2 - t_1) \rightarrow 0$. Thus, $\Psi : \Xi \rightarrow \Xi$ is equicontinuous.

Now, we are ready to show the existence of local mild solution.

By Leray-Schauder Fixed Point Theorem, there exists a fixed point, thus, a mild solution to Problem (3.1) over $[t_0, t_0 + \delta]$ with given initial value $v_{t_0} = v_0$. In particular, t_0 can be set to 0.

Replace t_0 by $t_0 + \delta$, v_{t_0} by $v_{t_0+\delta}$, there exists $\tilde{\delta} > 0$ such that we can extend the solution to $[t_0, t_0 + \delta + \tilde{\delta}]$. Repeat this process, in the end, we can get a maximal semi-closed interval $[0, T_1) \subset [0, T]$ over which a mild solution exists.

In the following two steps, we will show that $[0, T_1)$ can be extended to $[0, T]$, and, thus, get the mild solution we want.

3.2.6. *Step 6.* In this part, we show that if $[0, T_1]$ cannot be extended, then $\lim_{t \rightarrow T_1^-} E\|v_t\|^2 = \infty$.

First, we show that if $[0, T_1]$ cannot be extended, then $\limsup_{t \rightarrow T_1^-} E\|v_t\|^2 = \infty$. If not, then there exists a constant $0 < r(T_1) < \infty$ such that $\sup_{t \rightarrow T_1^-} E\|v_t\|^2 < r(T_1)$.

Denote

$$M(T_1) = \sup_{0 < t < T_1 + \delta_2} \|G_t\|$$

$$\Gamma_1(T_1) = \sup_{0 < t < T_1 + \delta_2} \{E\|\Delta_t(v_t)\|^2 \mid E\|v_t\|^2 \leq r(T_1)\}$$

$$\Gamma_2(T_2) = \sup_{0 < t < T_1 + \delta_2} \{E\|\Sigma_t(v_t)\|^2 \mid E\|v_t\|^2 \leq r(T_1)\}$$

where δ_2 is chosen so that $T_1 + \delta_2 \leq T$. For $0 < t^1 < t^2 < T_1$,

$$\lim_{t^1, t^2 \rightarrow T_1^-} E\|v_{t^1} - v_{t^2}\|^2 = 0,$$

since

$$\begin{aligned} E\|v_{t^1} - v_{t^2}\|^2 &\lesssim \|G_{t^1} - G_{t^2}\|^2 E\|v_{t_0}\|^2 + M(T_1)^2 \Gamma_1(T_1)(t^2 - t^1) + M(T_1)^2 \Gamma_1(T_1) \int_0^{t^1} \|v_{t^1} - v_{t^2}\|^2 ds \\ &\quad + \Theta M(T_1)^2 \Gamma_2(T_1)(t^2 - t^1) + \Theta M(T_1)^2 \Gamma_2(T_1) \int_0^{t^1} \|v_{t^1} - v_{t^2}\|^2 ds, \end{aligned}$$

the right hand side above tends to zero due to the continuity of G_t in the uniform operator topology for $t > 0$ which follows from the compactness of G_t . Thus, $\lim_{t \rightarrow T_1^-} E\|v_t\|^2$ exists.

Now, let's show that if $[0, T_1)$ cannot be extended, $\lim_{t \rightarrow T_1^-} E\|v_t\|^2 = \infty$.

If not, then there exists a constant $0 < r < \infty$ and a sequence $t_n \rightarrow T_1$ such that $E\|v_{t_n}\|^2 < r$.

Denote

$$\tilde{M} = \sup_{0 < t < T_1} \|G_t\|$$

$$\tilde{\Gamma}_1 = \sup_{0 < t < T} \{E\|\Delta_t(v_t)\|^2 \mid E\|v_t\|^2 \leq 3\tilde{M}^2(r+1)\}$$

$$\tilde{\Gamma}_2 = \sup_{0 < t < T} \{E\|\Sigma_t(v_t)\|^2 \mid E\|v_t\|^2 \leq 3\tilde{M}^2(r+1)\}$$

Now, $t \mapsto E\|v_t\|^2$ is continuous and $\lim_{t \rightarrow T_1^-} E\|v_t\|^2 = \infty$, thus we can find $\{l_n\}_n$ such that $0 < l_n < T - t_n$, $E\|v_t\|^2 \leq 3\tilde{M}^2(r+1)$ for any $t \in [t_n, t_n + l_n]$ and $E\|v_{t_n+l_n}\|^2 = 3\tilde{M}^2(r+1)$.

Then

$$\begin{aligned} 3\tilde{M}^2(r+1) &= E\|v_{t_n+l_n}\|^2 \leq 3E\|G_{t_n}v_{t_n}\|^2 + 3E\left\|\int_{t_n}^{t_n+l_n} G_{t_n+l_n-s}\Delta_s(v_s)ds\right\|^2 \\ &\quad + 3E\left\|\int_{t_n}^{t_n+l_n} G_{t_n+l_n-s}\Sigma_s(v_s)dW_s\right\|^2 \\ &< 3\tilde{M}^2r + 3\tilde{M}^2\tilde{\Gamma}_1l_n + 3\Theta\tilde{M}^2\tilde{\Gamma}_2l_n, \end{aligned}$$

and the right hand side of the last inequality tends to 0 as $n \rightarrow \infty$, which implies that \tilde{M} is less than 0, contradiction.

Thus, we can conclude that if $E\|v_{T_1}\|^2 < \infty$, then $[0, T_1)$ can be extended.

3.2.7. *Step 7.* In this part, we show that under the assumptions of our models $E\|v_{T_1}\|^2 < \infty$, thus, conclude that the mild solution is defined across the whole $[0, T]$.

Assume that $T_1 \neq T$,

$$\tilde{M} = \sup_{t \in [0, T]} \|G_t\|^2$$

$$s_1 = \max_{t \in [0, T]} f_1$$

$$s_2 = \max_{t \in [0, T]} f_2$$

$$s_3 = \max_{t \in [0, T]} \tau_1$$

$$s_4 = \max_{t \in [0, T]} \tau_2.$$

Then

$$\begin{aligned} E\|v_{T_1}\|^2 &\leq 3E\|G_{T_1}v_0\|^2 + 3E\left\|\int_0^{T_1} G_{T_1-s}\Delta_s(v_s)ds\right\|^2 + 3E\left\|\int_0^{T_1} G_{T_1-s}\Sigma_s(v_s)dW_s\right\|^2 \\ &\leq 3\tilde{M}^2E\|v_0\|^2 + 3\tilde{M}\int_0^{T_1} E\|\Delta_s(v_s)\|^2ds + 3\Theta\tilde{M}\int_0^{T_1} E\|\Sigma_s(v_s)\|^2ds \\ &\leq \{3\tilde{M}^2E\|v_0\|^2 + 3\tilde{M}^2s_2T_1 + 3\Theta\tilde{M}^2s_4T_1\} + \{3\tilde{M}^2s_1 + 3\Theta\tilde{M}^2s_3\} \cdot \int_0^{T_1} E\|v_s\|^2ds, \end{aligned}$$

denote $\{3\tilde{M}^2E\|v_0\|^2 + 3\tilde{M}^2s_2T_1 + 3\Theta\tilde{M}^2s_4T_1\}$ as Π_1 , $\{3\tilde{M}^2s_1 + 3\Theta\tilde{M}^2s_3\}$ as Pi_2 , then by Gronwall's inequality, we get

$$E\|v_{T_1}\|^2 \leq \Pi_1 \cdot e^{\Pi_2 T_1} < \infty.$$

Thus, by the result of Step 6, we have shown the existence of mild solution to Problem (3.1).

4. A SPECIAL CASE: ORNSTEIN-UHLENBECK PROCESS

In our models, there is a quite unnatural condition: $E\|\Sigma_t\|^p$ is uniformly bounded where $p \geq 4$. Usually an assumption on the existence of second moment is more realistic, however, due to the complicated correlation between the interest rate process and the stochastic volatility process, to achieve such a goal, we need to put stronger constrains. Two possible ways are:

- 1) Every sample path of Σ_t is bounded by some fixed constant.
- 2) $\mathbb{P}(\|\Sigma_t\|^2 \geq N)$ decays fast enough as $N \rightarrow \infty$.

Notice that if 1) is true, then clearly $E\|\Sigma_t\|^2$ is uniformly bounded. However, this is still a too strong condition. In the following, let's focus on case 2).

In general, 2) is not satisfied, however in the case of an Ornstein-Uhlenbeck process, under some natural condition, it can be achieved. Let's first consider Model 1 to illustrate the idea.

Assume that the process σ_t satisfies:

$$d\sigma_t = \bar{A}\sigma_t + d\bar{W}_t,$$

where \bar{W}_t is a \bar{Q} -Wiener process valued in real separable Hilbert space \bar{U} and \bar{A} generates strongly continuous contraction semigroup: \bar{G}_t . Then $\sigma_t = \bar{G}_t\sigma_0 + \int_0^t \bar{G}_{t-s}d\bar{W}_s$, and $\int_0^t \bar{G}_{t-s}d\bar{W}_s$ is continuous martingale. Its local covariance operator \bar{Q}_t is $\bar{G}_t\bar{Q}\bar{G}_t^*$, and notice that $Tr\bar{Q}_t = \|\bar{G}_t\|_{L_2(\bar{U}, L_2(\mathbb{L}, \mathbb{R}))}^2 \leq \|\bar{G}_t\|^2 Tr(\bar{Q}) \leq Tr(\bar{Q})$, which is obviously finite.

The following lemma will be used to control the decay of tail probability of process Σ_t .

Lemma 4.1. (Lemma 6.2 Chapter 7 [5]) *Let M_t be a continuous H -valued martingale over $[0, T]$ with the local covariance operator Q_t such that*

$$\sup_{0 \leq t \leq T} TrQ_t \leq N, a.s.,$$

for some $N > 0$. Then the following estimate holds

$$\mathbb{P}\{\sup_{0 \leq s \leq t} \|M_s\| \geq r\} \leq \exp\{-\frac{r^2}{4Nt}\},$$

for any $t \in (0, T]$ and $r > 0$.

Notice that our construction of σ_t in this section satisfies conditions of Lemma 4.1.

Based on the proof of the main theorem, for Model 1, we only need to estimate the expectation in the following form

$$E\|\sigma_t|v_t^\beta\|_{\mathbb{L}_2}^2 = E[\|\sigma_t\|_{\mathbb{L}_2}^2 \cdot \| |v_t^\beta| \|_{\mathbb{H}}^2] \leq 2E[\|\bar{G}_t\sigma_0\|_{\mathbb{L}_2}^2 \cdot \| |v_t^\beta| \|_{\mathbb{H}}^2] + 2E[\| \int_0^t \bar{G}_{t-s}d\bar{W}_s \|_{\mathbb{L}_2}^2 \cdot \| |v_t^\beta| \|_{\mathbb{H}}^2],$$

clearly $2E[\|\bar{G}_t\sigma_0\|_{\mathbb{L}_2}^2 \cdot \| |v_t|^\beta \|_{\mathbb{H}}^2]$ is finite. For the other component, we can apply Lemma 4.1. By our construction, there exists positive constant $N > 0$ which is an upper bound of the local covariance operator, thus

$$\mathbb{P}\left\{\sup_{0 \leq s \leq T} \|M_s\| \geq r\right\} \leq \exp\left\{-\frac{r^2}{4NT}\right\},$$

where $M_t = \int_0^t \bar{G}_{t-s} d\bar{W}_s$.

Set $E_i = \{\omega \in \Omega \mid i \leq \sup_{t \in [0, T]} \|M_t\| < i + 1\}$ to be an event set, $q_i = \mathbb{P}(E_i)$, for $i = 1, 2, 3, \dots, n, \dots$, then $\sum_{i=1}^{\infty} q_i = 1$. Thus, $E[\|\int_0^t \bar{G}_{t-s} d\bar{W}_s\|_{\mathbb{L}_2}^2 \cdot \| |v_t|^\beta \|_{\mathbb{H}}^2] = \sum_{i=1}^{\infty} E[\{\|\int_0^t \bar{G}_{t-s} d\bar{W}_s\|_{\mathbb{L}_2}^2 \cdot \| |v_t|^\beta \|_{\mathbb{H}}^2\} | E_i] \cdot q_i$.

Then

$$\begin{aligned} E\left[\left\|\int_0^t \bar{G}_{t-s} d\bar{W}_s\right\|_{\mathbb{L}_2}^2 \cdot \| |v_t|^\beta \|_{\mathbb{H}}^2\right] &\leq \sum_{i=1}^{\infty} (i+1)^2 E[\| |v_t|^\beta \|_{\mathbb{H}}^2 | E_i] \cdot q_i \\ &= \sum_{i=1}^{\infty} (i+1)^2 \sqrt{q_i} \cdot E[\| |v_t|^\beta \|_{\mathbb{H}}^2 | E_i] \cdot \sqrt{q_i} \\ &\leq \sum_{i=1}^{\infty} (i+1)^2 \sqrt{3 \exp\left\{-\frac{i^2}{4NT}\right\}} \cdot E[\| |v_t|^\beta \|_{\mathbb{H}}^2 | E_i] \cdot \sqrt{q_i} \\ &\leq \sum_{i=1}^{\infty} (i+1)^2 \sqrt{3 \exp\left\{-\frac{i^2}{4NT}\right\}} \cdot \sqrt{E[\| |v_t|^\beta \|_{\mathbb{H}}^4 | E_i]} \cdot \sqrt{q_i}. \end{aligned}$$

Notice that $\bar{C} := \sum_{i=1}^{\infty} [(i+1)^2 \sqrt{3 \exp\left\{-\frac{i^2}{4NT}\right\}}]^2 < \infty$, and

$$\sum_{i=1}^{\infty} [\sqrt{E[\| |v_t|^\beta \|_{\mathbb{H}}^4 | E_i]} \cdot \sqrt{q_i}]^2 = E[\| |v_t|^\beta \|_{\mathbb{H}}^4] \lesssim E[\| |v_t|^2 \|_{\mathbb{H}}^2]^\beta \leq \infty,$$

see Step 4 in the proof of the main theorem.

Thus, we can apply Cauchy-Schwartz inequality for countably infinite sum, and get

$$\begin{aligned} E\left[\left\|\int_0^t \bar{G}_{t-s} d\bar{W}_s\right\|_{\mathbb{L}_2}^2 \cdot \| |v_t|^\beta \|_{\mathbb{H}}^2\right] &\leq \sqrt{\bar{C}} \cdot \sqrt{E[\| |v_t|^\beta \|_{\mathbb{H}}^4]} \\ &\lesssim E[\| |v_t|^\beta \|_{\mathbb{H}}^4]^{1/2} \lesssim E[\| |v_t|^2 \|_{\mathbb{H}}^2]^{1/2} \lesssim E[\| |v_t|^2 \|_{\mathbb{H}}^2] + 1, \end{aligned}$$

thus, we can get all the necessary estimations. Moreover, replace $|v_t|^\beta$ by $| |v_t|^\beta - |v_{t_n}|^\beta |$, we can show that the map Ψ is still continuous.

For Model 2, we essentially use the same ideas and proofs as above, with the exception that $E\|\sigma_t\|_{\mathbb{L}_2}^2$ must be replaced by $E\|P(\sigma_t)\|_{\mathbb{L}_2}^2$ which is then bounded from above by a function of $E\|\sigma_t\|_{\mathbb{L}_2}^{2d}$ where $d = \text{degree of } P$. This allows us to reduce p to $2d$ in this special case.

5. REGULARITIES

In the general case, it is not easy to discuss regularity of the mild solutions. In this section, inspired by [3] and [6], we consider a very special model with simple stochastic volatility operators and show some related regularity properties.

Let's first state the model:

$$\mathbb{H}_k = L^2([0, 1], e^{\frac{2x}{k}} dx), k > 0;$$

$A_k = k \frac{\partial^2}{\partial x^2} + \frac{\partial}{\partial x}$ on \mathbb{H}_k , and the n th eigenfunction of A_k is $e_n = \sqrt{2} \sin(n\pi x) e^{-\frac{x}{k}}$ while the n th eigenvalue is $-\lambda_n$ with $\lambda_n = \frac{1}{2k}(1 + \pi^2 k^2 n^2)$;

$W_k(t)$: \mathbb{H}_k -valued, Q_k -Wiener process such that

$$W_k(t) = \sum_{i=1}^{\infty} \sqrt{\phi_i} W_k^i(t) e_i, \quad Tr Q_k = \sum_{i=1}^{\infty} \phi_i < \infty,$$

where $\{W_k^n(t)\}_{n=1}^{\infty}$ are independent identical one-dimensional Brownian motion.

The Model is

$$g_t(x) = \sum_{n=1}^{\infty} \sqrt{\phi_n} g_n(t) e_n(x),$$

where

$$dg_n(t) = -\lambda_n g_n dt + |\sigma_n(t)| dW_k^n(t),$$

with $g_n(0)$ and $g(0)$, all being deterministic and smooth enough, for instance, where $\sigma_n = \frac{1}{n^{\xi}} f_n(t)$, and

$$df_n(t) = b_n(t, f_n(t))dt + \eta_n(t, f_n(t))dB_n(t),$$

such that

1). b_n and η_n satisfy the standard linear growth and Lipschitz conditions and put some uniform bound on the initial values: for any n , $E\|f_n(0)\|^2 \leq \bar{O}$.

2). $\{B_n(t)\}_{n=1}^{\infty}$ are also independent identical one-dimensional Brownian motion, and, together with $\{W_k^n(t)\}_{n=1}^{\infty}$, they generates the filtration.

Then we can immediately conclude that

- 1). There exists a constant $\tilde{O} > 0$ such that for any t, n , $E\|f_n(t)\|^2 \leq \tilde{O}$;
- 2). $E[\int_0^t e^{-\lambda_n(t-s)} |f_n| dW_n^k]^2 \leq \tilde{O} \int_0^t e^{-2\lambda_n(t-s)} ds = \tilde{O}(\frac{1-e^{-\lambda_n t}}{2\lambda_n})$ by Ito isometry and 1).

Now, let's investigate our model.

5.1. In this first part, let's show that g_t is well-defined.

It's clear that g_t is \mathcal{F}_t -adapted and continuous (notice that this is due to the fact that we can always replace the resulting process by their continuous version if necessary), thus, we only need to show that for any t , $g_t \in L^2(\Omega, \mathbb{H})$. For simplicity, without loss of generality (WLOG), we may assume that $g_t(0) = 0$. Then for any t , assume that either $Q_k = I$ or $Tr(Q_k) < \infty$, then

$$\begin{aligned} E\|g_t\|_{\mathbb{H}_k}^2 &= E\left\| \sum_{n=1}^{\infty} \sqrt{\phi_n} g_n(t) e_n(x) \right\|_{\mathbb{H}_k}^2 = \sum_{n=1}^{\infty} \phi_n E[g_n(t)^2] = \sum_{n=1}^{\infty} \phi_n E\left[\int_0^t e^{-2\lambda_n(t-s)} |\sigma_n(s)| dW_n^k(s) \right]^2 \\ &\leq \sum_{n=1}^{\infty} \phi_n \frac{\tilde{O}}{n^{2\zeta}} \frac{1}{2\lambda_n}, \end{aligned}$$

which is finite under our assumptions.

5.2. Assume that either $Q_k = I$ or $Tr Q_k < \infty$, then for any t , $g_t(x)$ as a function of x , with probability one, is k times differentiable, $k < \zeta$.

Proof. For simplicity, WLOG, assume that $g_0 = 0$. Soblev Space $H^\zeta([0, 1], e^{\frac{2x}{k}} dx)$ is defined as

$$h \in H^\zeta \iff h \in \mathbb{H}_k \text{ and } \|h\|_{H^\zeta}^2 = \sum_{n=1}^{\infty} n^{2\zeta} \cdot |\langle h, e_n \rangle|^2 < \infty.$$

Now

$$\begin{aligned} E\|g_t\|_{H^\zeta}^2 &= E\left\{ \sum_{n=1}^{\infty} \phi_n n^{2\zeta} |g_n(t)|^2 \right\} = \sum_{n=1}^{\infty} n^{2\zeta} E[|g_n(t)|^2] \phi_n \\ &= \sum_{n=1}^{\infty} \phi_n E\left[\int_0^t e^{-\lambda_n(t-s)} |f_n(s)| dW_n^k(s) \right]^2 \leq \sum_{n=1}^{\infty} \phi_n \tilde{O} \frac{1}{2\lambda_n} < \infty. \end{aligned}$$

□

5.3. (This is a modified version of Lemma 5.21 Chapter 5 [6]) If $Tr Q_k < \infty$ or $\sum_{n=1}^{\infty} \frac{\phi_n}{n^{2\zeta} \lambda_n^{(1-\gamma)}} < \infty$, $\gamma \in (0, 1)$, then for any x and $y \in [0, 1]$,

$$E|g_t(x) - g_t(y)|^2 \lesssim |x - y|^{2\gamma},$$

in particular, if $\gamma > \frac{1}{2}$, then g_t is $\frac{2\gamma-1}{2}$ -Hölder continuous by Kolmogorov's test for random fields.

Proof. For any n , $e_n = \sqrt{2} \sin(n\pi x) e^{-\frac{x}{k}}$, thus, it's clear that there exists $\kappa > 0$ such that

$$|e_n(x)| \leq \kappa, \quad |\nabla e_n(x)| \leq \kappa \lambda_n^{\frac{1}{2}},$$

thus, $|e_n(x) - e_n(y)| \leq \kappa \lambda_n^{\frac{1}{2}} |x - y|$.

Then one can show that

$$|e_n(x) - e_n(y)| \leq \kappa 2^{1-\gamma} \lambda_n^{\frac{\gamma}{2}} |x - y|^\gamma.$$

Now notice that

$$\begin{aligned} g(t) &= \sum_{n=1}^{\infty} \sqrt{\phi_n} g_n(t) e_n(t) = \sum_{n=1}^{\infty} \sqrt{\phi_n} [g_n(0) e^{-\lambda_n t} e_n(x) + \int_0^t |\sigma_n(s)| e^{-\lambda_n(t-s)} dW_k^n(s)] \\ &= \sum_{n=1}^{\infty} \sqrt{\phi_n} g_n(0) e^{-\lambda_n t} e_n(x) + \sum_{n=1}^{\infty} \sqrt{\phi_n} \int_0^t |\sigma_n(s)| e^{-\lambda_n(t-s)} dW_k^n(s) =: I + II, \end{aligned}$$

where I represents the drift part and II represents the diffusion part. Clearly the drift part is smooth. Then, to investigate regularity, we only need to consider the diffusion part of our model

$$E\|g_t(x) - g_t(y)\|^2 = E\left[\left(\sum_{n=1}^{\infty} \sqrt{\phi_n} g_n(t) (e_t(x) - e_t(y))\right)^2\right].$$

However, for any n , $E[g_n(t)] = 0$ (notice that this is only used when $g_n(0)$ are not all zero), indeed, since we assume that $g_n = 0$ which implies that g_n is a martingale, and also notice that for any $n \neq m$, $g_n(t) \perp g_m(t)$ since all the one-dimensional Brownian motions are independent with each other. Thus,

$$\begin{aligned} E\left[\left(\sum_{n=1}^{\infty} \sqrt{\phi_n} g_n(t) (e_t(x) - e_t(y))\right)^2\right] &= \sum_{n=1}^{\infty} \phi_n \cdot |e_n(x) - e_n(y)|^2 \cdot E(g_n^2(t)) \\ &\leq \sum_{n=1}^{\infty} \phi_n \cdot \kappa^2 \cdot 4^{1-\gamma} \lambda_n^\gamma |x - y|^{2\gamma} \cdot \frac{1}{2n^{2\zeta} \lambda_n} = 2^{1-2\gamma} \cdot \kappa^2 \left(\sum_{n=1}^{\infty} \frac{\phi_n}{n^{2\zeta} \lambda_n^{1-\gamma}}\right) \cdot |x - y|^{2\gamma} \\ &\lesssim |x - y|^{2\gamma}. \end{aligned}$$

□

Based on sections 5.2 and 5.3, we can see that if $TrQ_k < \inf$ or $Q_k = I$, the mild solution is indeed a strong one, which inspires us to develop efficient numerical methods for implementation in the coming papers.

6. CONCLUSION

We showed the existence of mild solution to the Cauchy problem of Hilbert-space valued stochastic differential equations with stochastic volatility operators, modeling the evolution of instantaneous forward rate curves. Moreover, the stochastic volatility operator processes we proposed here related the volatility operators with the level of the forward rates to the power of some fraction number $\beta < 0.5$ ($\beta < 1$ under certain conditions), which are analogs to the well-known SABR model in finite dimension case. By examining some specific models, we showed regularity properties of the solutions with the help of a second order differential operator as the regularity term. As mentioned in [18], the regularizing term $D(x)\frac{\partial^2}{\partial x^2}$ has strong physical meaning. In particular, $D(x)$ represents a "force" to dampen the curvature of the interest rate curve in the long run and reduce its oscillation. It is technically not "risk-neutral" but its presence, which is confirmed statistically, cannot really be arbitrated, due to the bid/ask spread.

Let's discuss here some potential generalizations and applications of our two models.

We believe that the kind of methodology introduced in this article - Hilbert spaced-valued stochastic processes with stochastic volatility operator - has applications in much wider areas beyond financial math. For instance, it could be applied to the equations modeling the temperature of complex systems. Leray-Schauder theorem, following the proof of a priori inequality, is a very powerful tool that has been applied in other areas and has numerous fields of application to be explored in the context of infinite dimensional stochastic processes.

Numerical implementation is crucial for applied science. Appropriate numerical methods need to be designed to implement the model. One of the state-of-art technique that people usually apply to solve this type of problem is the Galerkin method [9] which uses finite sub-space to approximate the infinite Hilbert space. However, most of the present research only deals with deterministic volatility operator case. Thus, a study on this direction would raise people's interest from both practical and theoretical aspects.

Third, notice that in our present model the second order differential operator $D(x)\frac{\partial^2}{\partial x^2}$ is time-independent. However, due to its physical interpretation, there is no reason to keep this constrain, and in fact there is strong empirical evidence to support the time-dependence assumption. In a forthcoming paper, we envision to study the case of a time-dependent second order differential operator $D(t, x)\frac{\partial^2}{\partial x^2}$. Our results can be easily generalized to this situation under certain mild conditions.
